A: You can add a new layer of columns by creating an expression in the model tab. In this example, I have added a column 'DATE' which is simply the current date. Expression `GENDER=="Female" & DATE==TODAY()` Name I believe the name of the new column is listed on the left in the top menu bar. Location Apologies if this is a silly question, but as a relative newcomer to statistical analysis, I don't know what to do about it when I hit this sort of thing: - 90% of the respondents were male. -

Female's average salary was around \$200k/year. - Male's average salary was around \$50k/year. - When asked about this problem, the man responded that he was confused because he had thought that the male students' average salary was \$50k while the female students' average salary was \$200k. How do you deal with this? I know you can probably only generalize (as you do in all of your posts) but are there any statistics that you know about? I would hate to give bad advice if I'm making assumptions

that aren't true. Can I ask you how you made that decision? I would guess that the actual average would not differ, but the percentages would. – The Algebraist Oct 26 '12 at 2:14 @TheAlgebraist I'm sorry. I'm still a bit new to this. I'm really new to statistics, so I have a lot of trouble thinking about how to go about data like this. I know you can't generalize, but that is the best way to think about it. Bart Oct 26 '12 at 4:22 The problem with this is that the actual average salaries do not differ. If we count the actual number of people who work at each salary then the average is lower for the women. In this case the difference is that the women work at more of the lower salaries. This is due to sampling and so by this measure there is a slight difference in average salaries, but it is so small that it is not obvious. Njollster Oct 26 '12 at 14:11 I would go about this by looking at the most recent data. If the difference has gone up, there must be a reason. (For example, since the minimum 82157476af
